Integers

- The set of integers is denoted by \mathbb{Z} .
- Integers include:

$$\dots, -3, -2, -1, 0, 1, 2, 3, \dots$$

- Formally, $\mathbb{Z} = \{\dots, -2, -1, 0, 1, 2, \dots\}$.
- Common properties:
 - \mathbb{Z} is infinite and unbounded in both the negative and positive directions.
 - Closed under addition, subtraction, and multiplication:

$$\forall a, b \in \mathbb{Z}, \quad a \pm b \in \mathbb{Z}, \quad a \cdot b \in \mathbb{Z}.$$

- The quotient of any two integers is not necessarily an integer. So we need to extend arithmetic to **rational numbers**

Rational Numbers

- The set of rational numbers is denoted by \mathbb{Q} .

- Definition:

$$\mathbb{Q} = \left\{ \frac{p}{q} \mid p \in \mathbb{Z}, q \in \mathbb{Z}, q \neq 0 \right\}.$$

- Every integer is also a rational number (e.g., $5 = \frac{5}{1}$).

- Examples:

$$\frac{1}{2}, \quad -\frac{3}{4}, \quad 0, \quad 7, \quad \frac{11}{5}, \dots$$

- Properties:

- Closed under addition, subtraction, multiplication, and division (except division by zero).
- Densely packed on the number line: between any two rationals, there is another rational.

Interesting Facts

- Why division by zero is prohibited ?
 - Division is inverse of multiplication in the sense

$$\frac{m}{n} \cdot n = m$$

- if $n = 0$ and $m = 1$, we get $\frac{1}{0} \cdot 0 = 1$ which is nonsensical as any number multiplied by zero is zero
- Rational numbers suffice for all actual physical measurements like weight, height and length
- But Geometry, Algebra and Calculus force us to consider **real numbers**

A Real Number Line

Some rational numbers on the real line.

- if n is a positive integer then $\frac{1}{n}$ is to the right of 0 by the length obtained by dividing the segment from 1 to 0 into n segments of equal length

Is every Real Number a Rational

- $c^2 = a^2 + b^2$. If $a = 1, b = 1$ then $c^2 = 2$. Then what rational number is c
- By trial and error let assume $c = \left(\frac{99}{70}\right)^2 = \frac{9801}{4900}$ where the numerator just misses twice the denominator by 1
